Background & objectives: The mature fruits of Solanum nigrum contain steroidal glycosides. These are often used as vegetable and there are evidences on tribal use of these fruits as an oral contraceptive. The present study was carried out to evaluate the estrogenic potential of S. nigrum fruits by in vitro and in vivo assays.

Methods: Defatted methanol extract of dried S. nigrum fruits was column fractionated and the glycoside positive fractions pooled. Definite concentrations of the fraction were used for in vitro and in vivo assays. The effect on cell viability was analyzed in MCF-7 cell lines by MTT assay followed by in vitro evaluation of estrogenicity by hydroxy apatite (HAP) binding assay. The results were further evaluated in vivo by performing uterotrophic assay in ovariectomized mouse models.

Results: At low concentration (40 µg/ml), SNGF induced a dose-dependent increase in MCF-7 cell proliferation, while higher extract concentrations (80-320 µg/ml) caused progressive cell growth inhibition. The competitive binding assay using 3H-E2 suggests that this effect is mediated by estrogen receptor. Mouse uterotrophic assay revealed a classical uterotrophic response in ovariectomized mice in response to S. nigrum glycoside fraction (SNGF). SNGF at a dose of 100 mg/kg of body wt induced the maximum height of luminal epithelial cells which indicated an increase of 30.8 per cent over control (P<0.01) with a correlated increase in uterine wet wt (150% increase over control). Higher doses (250 and 500 mg/kg body wt) of SNGF did not induce any uterotrophic effect.

Interpretation & conclusions: Our preliminary data demonstrate the hormone like activity of Solanum glycosides both in vitro and in vivo in mouse, which needs to be further explored to evaluate the possible mechanism and clinical implications.

Key words Estrogen receptor - glycosides - Solanum nigrum - solasodine - uterotrophic assay
fruits of *S. nigrum* are used as an oral contraceptive, and the plant is one of the main constituents of plant based remedy prescribed for dysfunctional uterine bleeding. The medicinal effects of the plant are attributed to the presence of solasodine, a steroid glycoalkaloid, which is a potential alternative to diosgenin for commercial synthesis of various steroidal drugs. Solasodine in the plant is bound to a series of sugar residues attached to the oxygen atom at C-3; most common forms are the triglycosides and solamargine. The biological effect of mixture of *Solanum* glycosides is restricted to studies on certain basal cell carcinomas. There is one report of the presence of estrogen receptor (ER)-like proteins and endogenous ligands for ER in *S. glaucophyllum*. The present study was primarily aimed at assessing the estrogenic potential of the fruits of this edible and medicinal *Solanum* species- *S. nigrum*, in vitro in MCF-7 cell lines and in vivo in animal model.

**Material & Methods**

**Plant material:** Authentic certified seeds of *S. nigrum* (Acc No. IC 298650) procured from National Bureau of Plant Genetic Resources (NBPGR), Kerala Agricultural University Campus, Thrissur, Kerala, were planted and maintained in the green house of Rajiv Gandhi Centre for Biotechnology, Thiruvananthapuram, Kerala, under uniform conditions of temperature and humidity.

**Phytochemical extraction:** Mature, unripe fruits from two months old plants were collected, washed and oven dried at 60°C. Uniformly dried fruits were powderd and 100 g of dried powder was used for soxhlet analysis. Extraction was carried out sequentially with 1 ml ethanol. The stock containing the glycoside fraction was prepared in 100 mg/ml of DMSO [methyl sulfinyl methane, Sisco Research Laboratory (India)]. Five dilutions of the extract were prepared in serum free medium which include 1:500 (320 μg of SNGF), 1:1000 (160 μg of SNGF), 1:2000 (80 μg of SNGF), 1:4000 (40 μg of SNGF) and 1: 8000 (20 μg of SNGF). After allowing the cell lines to grow for a period of 48 h, the medium was removed and 100 µl each diluted SNGF was added in each well. After 48 h, the medium was replaced by MTT reagent [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide] dissolved in DMEM containing 2 per cent FBS and incubated at 37°C. The absorbance of the coloured solution was measured at 570 nm in a microplate reader (Bio-Rad, Model 680, USA).

**Evaluation of estrogenic activity in vitro by hydroxyapatite (HAP) binding assay:** HAP binding assay for estrogen receptor binding was carried out for assessing the estrogenic potential of SNGF on MCF-7 cell line. Commercially available HAP (Sigma, USA) was used in this assay. Aliquots containing 15 μg of protein (MCF-7 cytosol) were incubated overnight with varying concentrations of methanol extract and 20 nM final concentration of [1\(^\text{H}\)]-estradiol ([H-E\(_2\)]) ± 100 fold molar excess of diethylstilbestrol (DES) (Sigma, USA) at 4°C in a final volume of 200 μl. After overnight incubation, 250 μl of a 60 per cent HAP suspension in TEM buffer (pH 7.6) was added and the mixture was kept in ice for 15 min. After washing twice with ice cold TEM buffer, the HAP pellet, collected following centrifugation, was extracted with 1 ml ethanol.
radioactivity in the ethanol extract was measured. Non-specific binding was determined in the presence of a 100-fold excess DES and was subtracted from total binding.

_Evaluation in vivo on animal models:_ Swiss albino mice from Sree Chitra Thirunal Institute of Medical Science and Technology (SCTIMST), Thiruvananthapuram, Kerala, were housed within temperature controlled (22 ± 2°C) conditions in the animal house facility of Rajiv Gandhi Centre for Biotechnology, Thiruvananthapuram. Mice were maintained on a 12 h light: 12 h darkness photoperiod and food and water were available _ad libitum_. Female mice (3 months old, 20-25 g) were ovariectomized and rested for ten days before receiving treatment. The treatment groups were administered orally for seven days with 200 µl each of SNGF alone at concentrations of 100, 250 and 500 mg/kg body wt/day, distilled water alone (control group), or with 17β-estradiol (E₂) alone (Sigma, USA) at a dose of 1 mg/kg body wt, which served as the positive control group. After seven days, mice were weighed and sacrificed by cervical dislocation and their uteri were dissected out, blotted and the wet wt recorded. All the protocols for animal experiments were approved by the Ethics Committee for Animal Experiment of Rajiv Gandhi Centre for Biotechnology, Thiruvananthapuram.

_Histological analysis:_ The uteri were immediately fixed in 10 per cent formaldehyde. One horn of each uterus was dissected transversely and microtome sections of the tissues were stained by haematoxylin and eosin method. The sections were used for morphometric determination of changes in luminal epithelium.

_Morphometric analysis:_ The height of the luminal epithelium was determined using optical micrometer attached to the fluorescent microscope (Nikon Instruments Inc, NY, USA). Four measurements were made within four areas of each uterus.

_Statistical analysis:_ All experiments were performed in 5 replicates and results are presented as mean ± SEM. Data were analyzed by one-way ANOVA. The differences between treatments were tested by Fisher’s least significant difference test.

**Results & Discussion**

SNGF treatment at 40 µg/ml resulted in proliferation of MCF-7 cells, whereas it inhibited MCF-7 cell proliferation at concentrations ranging from 80 to 320 µg/ml (Fig. 1), which is 30 to 60 per cent lower than MCF-7 control. SNGF significantly inhibited the binding of [³H]-E₂ to cytosolic estrogen receptor in a dose dependent manner. The IC₅₀ value of SNGF is 40 ± 5 µg/ml (Fig. 2). The results of competitive binding assay using [³H]-E₂ suggest that stimulation of cell proliferation at low concentration is likely to be mediated via the estrogen receptor. This observation is in consonance with similar findings with soy isoflavone phytoestrogen, genistein. In a recent report, extracts of Chinese licorice (Glycyrrhiza uralensis) exhibited ER-dependent MCF-7 cell proliferation at low concentrations and an anti-proliferative activity at higher concentrations which was found to be ER-independent. Our observations in _S. nigrum_ are in agreement with these reports but further studies are needed to conclude whether the anti-proliferative activity is mediated via the estrogen receptor.

![Fig. 1. MTT assay shows proliferative effect of SNGF on MCF-7 cells at a concentration of 40 µg/ml concentration and an inhibition of cell proliferation at higher concentrations (80-320 µg/ml). The MCF-7 cells were treated with SNGF at concentrations ranging from 20-320 µg/ml. Values are means ± SE of 5 replicates.](image1)

![Fig. 2. HAP binding assay result shows that SNGF at a concentration of 40 µg/ml reduces the specific radioligand binding of the control (17 β - E₂) to the ER by 50 per cent.](image2)
proliferative activity of SNGF at higher concentrations is ER-independent.

The uteri from mice treated with 100 mg/kg of body wt appeared stouter and swollen, which upon sectioning, was found filled with fluid. Histological observations revealed that this lowest dose of SNGF induced the maximum height of luminal epithelial cells (Figs 3, 4b) which indicated an increase of 30.8 per cent over control ($P<0.01$), in addition to effecting stromal cell differentiation and glandular proliferation (Fig. 4c), which were not observed in uterus from control mice. Treatment with $E_2$ induced an increase of luminal epithelial cell height of 84.6 per cent (Fig. 3; $P<0.001$) over control (Fig. 4a). Higher concentrations did not affect a significant increase in cell height relative to control. The SNGF when fed to the ovariectomized mice at a concentration of 100 mg/kg body wt also significantly increased the wet wt of the uterus relative to the control group ($P<0.001$). There was a 150 per cent increase in uterine wet wt in response to 100 mg/kg concentration of extract and a 283 per cent increase in response to positive $E_2$ ($P<0.001$). Wet wt of the uterus calculated as a percentage of the body wt showed a similar change in pattern in response to treatment. Higher concentrations (250 and 500 mg/kg of body wt/day) of SNGF did not produce a significant increase in uterine wet wt compared to control (Fig. 5).

The uterotrophic assay has been traditionally used to establish the estrogenic effects of suspected

---

**Fig. 3.** Effect of SNGF on ovariectomized mouse uterine epithelial cells. Water fed ovariectomized mice served as control; treatment group mice were fed with 100, 250 & 500 mg/kg body wt of SNGF. They were sacrificed after 7 days of treatment and the uteri were collected. Result indicated an increase in uterine cell height of animals treated with 100 mg/kg SNGF which is 30.8 per cent more than the control. Values represent the mean ± SE values obtained from 5 animals per treatment. $P^{**}<0.01$, $P^{***}<0.001$ compared to control.

**Fig. 4.** Photomicrographs of Hematoxylin and Eosin (H&E) stained sections of ovariectomized Swiss albino mice. (a) Water vehicle (control); (b & c) treatment with 100 mg/kg of body wt of SNGF; (b) arrow shows increase in luminal epithelial cell height compared to control; (c) increase in gland number in response to SNGF (10X magnification).
Estrogens and is still used as a gold standard for in vivo assessment of estrogenic activity. The uterus responds to cyclical changes in estrogen and progesterone levels in preparation for embryo implantation and estrogen mediates the principal proliferative response of the uterus through the estrogen receptors\(^{14,15}\). In uterus, the physiological and genomic responses to estrogen have been described as biphasic. The events include hyperemia and uterine fluid uptake or water imbibition\(^{16}\). The water imbibition results in rapid increase in uterine wet wt. The late phase response to estrogen includes epithelial cell proliferation and differentiation\(^{17}\). SNGF at low concentrations displays uterotrophic activity that is not observed at higher concentrations which seems to depress the uterotrophic response to below the control levels. Similar observations from previous studies led to the conclusion that the uterotrophic and the estrogen agonistic effect presented by various natural estrogens occur at low doses only\(^{18-20}\). The results confirm the calabrese's concept of hormone-like biphasic dose response model which is characterized by a low-dose stimulation which usually present a modest response (30-60% vs. control) and a high-dose inhibition\(^{21-23}\) as revealed in our studies on *S. nigrum*, indicating that a classical uterotrophic response occurs in the mouse uterus in response to SNGF.

In conclusion, our data showed hormone like activity of *Solanum* glycosides indicated by their ability to bind estrogen receptor in vitro. SNGF is less active than E\(_2\), but has potencies comparable to other known phytoestrogens. Further studies need to be done to understand the mechanism and clinical implications.
