Testicular seminoma with early carcinomatous differentiation

Fig. 1. Giant testicular mass on physical examination (arrow).

Fig. 2. Computerized tomography of retroperitoneal lymphadenopathy. Arrow shows 10 × 9 cm mass.

Fig. 3. The tumour cells with cytoplasmic and perinuclear “dot-like” staining with podoplanin (×40).

A 25 year old male patient presented to the Urology Clinic, department of Urology, Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey, in March 2013, with painless testicular mass for the last three months. Physical examination revealed a 20×15 cm sized right testicular mass (Fig. 1). Computerized tomography showed 10×9 cm sized mass in the retroperitoneal area (Fig. 2). Serum tumour markers were measured. Serum alpha foeto protein (AFP), beta human chorionic gonadotropin (β-hCG) and lactate dehydrogenase (LDH) levels were 1.59 U/l, 16.34 IU/l and 955 U/l, respectively. The patient underwent inguinal surgical orchiectomy for definitive diagnosis and treatment. Macroscopically, this right testicular mass was 19×13×6 cm in size, that consisted of focal necrosis and haemorrhage. Infiltration of tunica albuginea with tumour cells was seen. Microscopically,
extensive necrosis, lymphovascular invasion, infiltration of rete testis, epididymis, tunica vaginalis and albuginea suggested the high mitotic activity of atypical seminoma. Immunohistochemically, the tumour cells were diffusely positive for podoplanin and focal positive for CD 30 (Fig. 3), but were negative for placental alkaline phosphatase (PLAP), c-kit CD117, CK(cytokeratin) 8/18, CK 19, high molecular weight cytokeratin (HMWCK) and pan-cytokeratin (PANCK). After pathological examination, the patient was treated with four cycles of bleomycin, etoposide and cisplatin chemotherapy and radiotherapy for para-aortic regimen with 3600 cGy. After this treatment, second line chemotherapy including paclitaxel, ifosfamide and cisplatin was performed. The patient was followed up for one year without recurrence and metastasis.

Atypical seminoma was defined as an intermediate neoplasm between embryonal carcinoma and classical seminoma. Tumour cells showing moderate or marked nuclear pleomorphism, nuclear overlapping, lack or paucity of cytoplasmic clarity were considered as atypical seminomas. All seminomas are not the same, rare cases may grow in a more aggressive manner than expected. Positive CD30 may be showing early carcinomatous differentiation of some seminomas. Early carcinomatous differentiation is an infrequent phenomenon, which can progress to advanced disease.
